ABSTRACT

Context Gastric duplication cysts are often associated with microscopic evidence of ectopic pancreatic tissue on its submucosal and less commonly subserosal surface. Case report We present an unusual case of a gastric duplication cyst with finger-like projections and a large heterotopic pancreas on the serosal surface of the cyst in a 30-year-old female. Conclusion An embryological explanation for the finger-like projections is given and a new addition to the morphological classification of duplication cyst is proposed.
