ABSTRACT
Case report We presented an unusual case of heterotopic pancreas found incidentally in the gallbladder, associated with gallbladder symptomatology, and high levels of amylasuria. Heterotopia was evidenced by histological study, showing the presence of acinar and ductal components of pancreas in the gallbladder body. Conclusions Despite its rarity, such a lesion requires consideration in the differential diagnosis of acalculous lesions of the gallbladder, especially when polypoid formations, and isolated parietal thickenings or nodulations are present. A review of the relevant literature is discussed following the presentation of this case.
